Utility Connections, Safety & Code Issues
How to plan for and design PV systems including Structural design considerations of basic PV systems, such as span or rafters, Wind forces, Gravity loads, Seismic forces
And information regarding relevant International Building Code (IBC) and ASCE7 structural engineering design manual, and the relationship to the utility grid and interconnection.
Grid Interconnection and Relationship to the Utility
A grid-connected solar PV system feeds **excess energy** directly into the grid, typically the public electricity grid. Grid-connected systems vary in size from residential of 2–10 kW, to solar power stations up to 10s of MW.

It is important to involve the utility early (in planning stages). Be aware of correct metering coordination and scheduling of hookup and utility rate schedules (such as net metering), activation with your contractors, as well as coordination between your Electrical Monitoring System (EMS), BAS, and other monitoring or dashboards on your on-site generation, and review what to expect in terms of billing with your utility rep for solar connections and the present owner.
Here is how the energy flows from the solar PV system through a string inverter.

The DC electricity produced from a PV system will first flow through a DC disconnect, then through the string inverter where it is converted to AC electricity. Then the AC electricity will flow through an AC disconnect, and then to the building’s service panel. The electricity will flow into the building if there is a demand at that moment, if not, the electricity will flow through the utility meter and to grid.

If the project is net metered, the electricity can be pulled back from the grid through the utility meter to the service panel, like normal.
Advantages to Grid Connection

Net metering and value-of-solar tariffs can offset a customer’s electricity usage costs.

Systems such as Net Metering and Feed-in Tariff which are offered by some system operators, can offset a customers electricity usage costs. In some locations though, grid technologies cannot cope with distributed generation feeding into the grid, so the export of surplus electricity is not possible.
Advantages to Grid Connection

Grid-connected PV systems do not require a battery system.

Grid-connected PV systems are comparatively easier to install as they do not require a battery system.
Electricity collected by solar panels starts out as “Direct Current” (DC) and must be converted to “Alternating Current” (AC) if it will be used in a building connected to the grid. An “INVERTER” converts the electricity from DC to AC.

The typical AC operating frequency is 60 Hertz (60 Hz) in the U.S. CURRENT is measured in Amps, with the unit Amp symbolized by a capital “A”. The voltage is measured in “Volts” (V). The product of current (amps) and voltage gives you power (in the units of “Watts” (W)).

Any connection of an electrical generation system such as a PV system required permitting and approval from the power company.

The Department of Energy has supported many projects intended to decrease costs and waiting time associated with grid-interconnection of PV systems.

On average, 1kw PV array would require approximately 100 square feet of roof space. Smart inverters improve grid resilience and improves grid power.
The inverter must monitor grid voltage, waveform, and frequency. For normal operation the inverter must synchronize with the grid waveform, and produce a voltage slightly higher than the grid itself, in order for energy to smoothly flow outward from the solar array.

Here in the photo we see **from left to right, the DC disconnect, two string inverters, the AC disconnect, and the service panel with the meter combined**. As previously mentioned, the DC electricity produced from a PV system will first flow through a DC disconnect, then through the string inverter where it is converted to AC electricity. Then the AC electricity will flow through an AC disconnect, and then to the building's service panel. The electricity will flow into the building if there is a demand at that moment, if not, the electricity will flow through the utility meter and to grid.

**Two different ways to connect:** (1) Load-side connection and utility-side connection. (2) It’s a financial contribution to the grid, and lowers your energy bill.

- A “feed in tariff” you sell ALL the power you make to the utility, and then you get a credit for what you put into the grid, so you don’t pay the utility for that.
“Islanding” is the condition in which a solar photovoltaic generator continues to power a location even though power from the electric utility grid is no longer present. Islanding can be dangerous to utility workers, who may not realize that a circuit is still powered, even though there is no power from the electrical grid. For that reason, solar PV inverters must detect islanding and immediately stop producing power; this is referred to as anti-islanding.

It’s so that the electricity has a place to go, and doesn’t end up in the inverter. So that if you lose energy connection, and since the panels are still making energy and sending it to the inverter. Inverters that are grid-interactive must have a feature to prevent islanding.

When the grid is down, the anti-islanding function within the inverter shuts down the inverter; you will not have the use of the solar electricity in the event of a grid failure.
With the anti-islanding mechanism, the inverter will stop converting DC to AC when the utility service is disconnected. This means the building will not be receiving power from the solar PV system when the utility grid does down.
To continue to receive power, the system will need to be paired with a battery back-up. The battery can either charge from the grid, or from the solar PV system.

In this diagram we can see the backup AC circuits will still receive power when the inverter stops converting the power. Note, the AC circuits are typically limited to emergency power only and not power for the entire building.
Design professionals should be advised that every location and jurisdiction will have its own variation for regulation of PV installations and possibly 'solar-ready'.
What Makes SOLAR Permitting Unique?

- Impacts multiple disciplines/areas of the building
- Most frequently retrofits
- Inexperience of code officials
- Rooftop access needed for inspection
- Wide variation in local permitting requirements

In a recent survey by ICC, over 80% of code officials surveyed report that they would benefit from training on conducting solar inspections.
In a recent survey by ICC, over 80% of code officials surveyed report that they would benefit from training on conducting solar inspections.
Clean Power Finance conducted a survey of installers and AHJs in 2012 to better understand the current state of solar permitting. It surveyed 273 residential installers, gathering data on 500+ installations spanning 12 states comprising over 90% of the residential solar market. Most notably, it found that:

- Permitting processes vary widely among locales and usually involve 2 distinct agencies (and up to 5 agencies), each with different processes.
- More than 1 in 3 installers avoid selling in an average of 3.5 jurisdictions because of associated permitting difficulties.
- AHJs require, on average, nearly 8 work weeks to complete their tasks. The staff time of the installer, however, averages just 14.25 hours.
- There are likely significant opportunities for installers to reduce costs by improving processes around customer acquisitions and operations.

While the situation has clearly improved somewhat in places like CA (as we’ll see later in this presentation), the problems remain.
The Problem from Both Perspectives

- Varying requirements across AHJs create confusion, rework, and frictional costs
- Requirements within the same AHJ suffer from inconsistent application.
- Requirements are not readily accessible and can be updated without notice.
- Inconsistent processing and cycle times disrupt sales and operations flows (e.g., scheduling staff time, routing crews, and site visits to customers)

Installer’s Perspective

“I find myself having to educate the city staff on their own requirements”

“AHJs can change their interpretations of existing codes and you only find out after you are about to submit your paperwork...”

The survey of Installers and AHJs conducted by the DOE and Clean Power Financing revealed some very clear differences between the two groups.

Along these lines, this presentation seeks to highlight the challenges experienced by both groups and steps code officials can take to improve solar permitting.

Solar Training for Code Officials is Happening

- Strong growth of the solar industry is expected to continue
- Many code officials recognize they need improved knowledge of solar
- Focus is now on reducing non-hardware costs

In a recent survey by ICC, over 80% of code officials surveyed report that they would benefit from training on conducting solar inspections.
What is “Expedited Permitting”? 

- Definition: An organized permitting process by which a majority of small PV systems can be permitted quickly and easily.
- Simple eligibility checklist to determine eligibility.
  - 10-15 kW maximum power output
  - Simplified structural and electrical review
  - Minimize the need for detailed engineering studies
  - Not intended to apply to all PV systems
  - Widespread use of expedited permitting and growing

Expedited permitting is a term that has become common in the solar industry. Bill Brooks, in the Solar ABCS Expedited Permit Process for PV Systems document defined it as follows:

“An organized permitting process by which a majority of small PV systems can be permitted quickly and easily”

For solar PV systems, this is often accomplished by establishing a simplified system of permitting for systems that meet key eligibility requirements that allow assurance of safety to be streamlined. Examples of these eligibility requirements include:

- Limited maximum power output or inverter rating.
- Simplified structural review through the use of engineered and listed racking systems and modules and limited, low-risk geometries. Simplified electrical review by limiting expedited permitting to certain system types, requiring listed electrical components and by adopting standardized submittal requirements.
- Limits or eliminates the need for detailed engineering studies in permitted structures that meet minimum codes and for specific, low-risk system designs.

Key point – expedited permitting is not intended to apply to all systems! For
more complex systems or those to be implemented on structures that were not permitted and constructed to modern building codes, a more detailed, tradition permitting approach will be necessary. For example, the criteria established in the Solar ABCs process are assumed to apply to approximately 90% of PV installations – primarily simple, residential installations.
Some Jurisdictions Offer Expedited Permitting

Eligibility requirements may include:
• A limit on system capacity and complexity
• Limit applicability to certain building types
• Installation by licensed solar contractors
• Utilize listed/certified components
• Exclude sites with special zoning, historical and architectural requirements

Since expedited permitting does not apply to all systems, criteria are needed to discriminate between those that are included and those that are not. This is often done by means of an eligibility checklist or series of questions. There are differences between the specific requirements to be eligible in different locations, but they follow several clear themes. And overall, the intent is to find those systems where the risk and complexity is low.

What kind of permits are required?
• City of Orlando requires a building and electrical permit for PV and a building and plumbing permit for Thermal.
  • For more information, visit the [City of Orlando permitting website](http://www.cityoforlando.net/wp-content/uploads/sites/29/2014/03/solar-submittal-checklist.pdf)
• Orange County requires an electrical permit for PV and a plumbing permit for Thermal.
  • For more information, visit the [Orange County permitting website](http://www.cityoforlando.net/wp-content/uploads/sites/29/2014/03/solar-submittal-checklist.pdf)
• St. Cloud requires an electrical permit for PV and a plumbing permit for Thermal.
  • For more information, visit the [St. Cloud permitting website](http://www.cityoforlando.net/wp-content/uploads/sites/29/2014/03/solar-submittal-checklist.pdf)
• Osceola County requires a building and electrical permit for PV and a building and plumbing permit for Thermal.
  • For more information, visit the [Osceola County permitting website](http://www.cityoforlando.net/wp-content/uploads/sites/29/2014/03/solar-submittal-checklist.pdf)
Ask AHJ if They Have a Solar Checklist

**BENEFITS TO DESIGNERS**
- Helps you prepare plans for application / inspections
- Helps you establish client/subcontractor expectations

**BENEFITS TO AHJs**
- Increase consistency of inspections
- Consolidate material from different depts/trades

**BENEFITS TO CONTRACTORS**
- Advance preparation for inspection
- Set expectations for subcontractors

A checklist can get all involved on the same page; helping to assure nothing falls through the cracks.
Codes and Standards Related to PV Systems

Design professionals should be advised that every location and jurisdiction will have its own variation for regulation of PV installations and possibly 'solar-ready'.
The ICC Codes are the basis for the code ordinances adopted by most jurisdictions.

The 2015 IECC includes an Appendix for residential solar-ready provisions. The 2018 IECC will include an Appendix for commercial solar-ready provisions. This PDF describes how all states adopt codes: https://www.iccsafe.org/gr/Documents/AdoptionToolkit/HowStatesAdopt_I-Codes.pdf

The current model building code adopted in each state are:

AZ: 2012 IBC / 2009 IRC. https://www.iccsafe.org/about-icc/government-relations/map/arizona/ Arizona is a home-rule state, and most building
codes are adopted at the local level; there is no statewide building code. However some state departments adopt specified codes for certain purposes (for example, AZ-Department of Health Services adopts a minimum code for licensed health care facilities statewide. AZ Department of Housing adopts minimum codes for manufactured housing; AZ- Office of the State Fire Marshal adopts a minimum state fire code.) For a list of jurisdiction adoptions, see https://www.iccsafe.org/about-icc/government-relations/map/arizona/ PHOENIX has adopted the "2012 Phoenix Building Construction Code (effective July 1, 2013) https://www.phoenix.gov/pdd/devcode/buildingcode ; To view City Council approved code amendments, per Ordinance G-6199, with an effective date of Nov. 1, click here .

CO: A home-rule state, there is no over-riding statewide code; codes are adopted locally by jurisdictions. A list of the codes adopted by jurisdictions is available here: https://www.iccsafe.org/about-icc/government-relations/map/colorado/ The 2016 Denver Building Code (DBC) (based on the 2015 ICC codes) was officially adopted by Denver’s City Council on Monday, March 7, 2016, and signed by Mayor Hancock on Thursday, March 10, 2016, and was amended Dec 19, 2016. For this reason, it is often called the "Denver Building Code Amendments" or "DBCA". https://www.denvergov.org/content/denvergov/en/denver-development-services/help-me-find-/building-codes-and-policies.html

DC: Effective statewide: 2012 IBC /IRC. Effective March 28, 2014, the District of Columbia adopted 11 of the 2012 ICC Codes and the NFPA’s 2011 NEC with changes, deletions, and/or additions set forth in the 2013 District of Columbia Construction Codes Supplement, 12 DCMR, Subtitles A through L. Updating of the Construction Codes is an ongoing function of the Construction Codes Coordinating Board (CCCB). In addition to the laws and regulations enforced by DCRA, numerous other agencies and entities, both local and federal, have jurisdiction over issues and matters related to buildings and structures in the District of Columbia. In October 2015, the Construction Codes Coordinating Board (CCCB) commenced a new code development cycle to review the 2015 ICC Codes and the 2014 NEC. For more information about the CCCB and its code development process, see the Construction Codes Coordinating Board website.

IN: **Effective statewide:** 2012 IBC / 2003 IRC.

IOWA: Iowa is a home-rule state and local jurisdictions are not required to adopt the most current version of the Iowa Code. The Iowa Code with amendments is based on the 2015 IBC / IRC. **CODES ENFORCED BY THE CITY OF DES MOINES EFFECTIVE March 1, 2017:** The following codes are adopted by reference with very few additions or deletions in the Municipal Code.

- 2015 INTERNATIONAL BUILDING CODE
- 2015 INTERNATIONAL RESIDENTIAL CODE
- 2015 INTERNATIONAL EXISTING BUILDING CODE

operation, servicing, installation, and manual criteria contained in the Operating Guidelines and Standards in subpart 4a. In addition, in accordance with the Operating Guidelines and Standards, every seller of solar collectors and solar water heating systems for installation in the state must provide every bona fide prospective buyer a copy of the certification award issued by the SRCC. Subp. 6. Enforcement. The building official shall not issue any permits required for installation of the electrical, mechanical, or structural aspects of the solar energy system until the seller has furnished the building official a copy of the completed certification award required by this part. The building official need not determine the accuracy of the seller's certification award or otherwise determine the extent to which the seller's solar energy system meets or exceeds the Operating Guidelines and Standards in subpart 4a." However, this part does not apply to solar energy systems whose primary purpose is to produce generated electric power. This part is to be used in conjunction with existing building codes and standards and does not replace existing building codes. Source: https://www.revisor.mn.gov/rules/?id=1325.1100

NM: 2015 NM Commercial Building Code (NMCBC) is based on the 2015 IBC and the NM Residential Building Code is based on the 2015 IRC. Both became effective Nov 15, 2016. However much of the code substitutes earlier code versions, so it’s not fully based on the 2015 I-codes. (i.e., the “Energy” section in IBC is based on the 2009 NM Energy Conservation Code; others based on 2012). A few local jurisdictions adopt codes under home rule. According to the NM HBA, through June 30, 2017 contractors may receive building permits that comply with either the 2009 or 2015 codes. http://www.nmhba.com/building-code-information/ Albuquerque has made some amendments to the state code. See the last bullet “City of Albuquerque Amendments to the NM Building Code” on this page: https://www.cabq.gov/planning/building-safety-permits/current-building-codes for the detailed list of the building code amendments.

TX: **2015 IRC.** Jurisdictions authorized by state law to adopt later editions of IBC, IRC, IPC, IMC, IFGC, and IECC. Because Texas is a home rule state, each local jurisdiction has to adopt the code by ordinance and provide enforcement. In the unincorporated areas of counties, builders are still responsible for meeting the requirements of the codes even though the counties do not have enforcement authority. Texas mandates building codes (except for the IECC) for all municipalities adopting codes, excluding most unincorporated areas. Municipalities can make local amendments and adopt newer editions of the IBC, IRC, and IECC. However, these codes must be implemented and enforced at the local level. [https://sll.texas.gov/law-legislation/building-codes/](https://sll.texas.gov/law-legislation/building-codes/)

**Houston:** The 2012 Construction Code Package became effective on February 1, 2016. The Houston Amendments to the current adopted codes are listed below. The amendments, along with the model codes, constitute the City of Houston Codes. **Note:** The City of Houston does not have the model codes available; they can be purchased through the respective publisher. [https://www.houstonpermittingcenter.org/code-enforcement/customer-assistance-code-development-cacd-section.html](https://www.houstonpermittingcenter.org/code-enforcement/customer-assistance-code-development-cacd-section.html)

**CONSTRUCTION CODE**

**Building:** 2012 IBC Houston Amendments _02/01/2016_
**Residential:** 2012 IRC Houston Amendments _02/01/2016_
**Electrical:** 2014 NEC Houston Amendments _09/24/2014_
**Mechanical:** 2012 UMC Houston Amendments _02/01/2016_
**Plumbing:** 2012 UPC Houston Amendments _02/01/2016_
**Fire:** 2012 IFC Houston Amendments _02/01/2016_

**LSB Standards - NOTE:** The LSB Standards are currently being reviewed for update to the 2012 Houston Adopted Construction Code.

**Residential Energy: Note:** The enforcement of Chapter 11 of the 2015 International Residential Code became mandatory by state law effective September 1, 2016.

**New 2015 IECC Amendments (Residential Provisions) - Effective October 24, 2016**
**Commercial Energy - Note:** The 2015 IECC-Commercial Provisions became effective November 1, 2016 per state law.

**New** [ASHRAE 90.1-2013 Amendments] 12/09/2016

**DALLAS: 2015 IBC with amendments**
[http://dallascityhall.com/departments/sustainabledevelopment/buildinginspection/Pages/construction_codes.aspx](http://dallascityhall.com/departments/sustainabledevelopment/buildinginspection/Pages/construction_codes.aspx)

The Washington State Building Code is comprised of several different codes. Most are national model codes adopted by reference and amended at the state level. Others, such as the Washington State Energy Code, are state-written state-specific codes.
The International Solar Energy Provisions incorporates all code provisions for both solar PV and solar thermal in one book. This is not really a separate code (does not contain any original information), it is a compendium of all provisions related to solar from the building, mechanical, plumbing, fire, energy AND electrical codes.

This is a tremendous resource to have on your shelf....and it’s less than $50.

Knowing that there is a one-stop resource for you to get all this information, we are quickly going to review what the code requirements for PV include and where they are located.
The code requirements pertaining to PV are found throughout many of the I-codes. For example, in the IBC and IRC you will find basic information on structural requirements, material standards including rating of roof coverings, and standards for roof construction.

The International Building Code (IBC) scope covers all buildings except detached one and two family dwellings and townhouses not more than 3 stories in height. The IBC contains safety concepts, structural, and fire and life safety provisions covering means of egress, comprehensive roof provisions, and innovative construction technology. The IBC includes requirements for the fire class rating of PV systems and wind load calculations. See Chapter 15 for roof penetrations and fire classification, and Chapter 16 for structural, wind and seismic concerns.

The International Residential Code (IRC) establishes minimum regulations for one- and two-family dwellings and townhouses up to three stories. It brings together all building, plumbing, mechanical, fuel gas, and energy and electrical provisions, which include PV systems for one- and two-family residences. See Chapter 9 for roof penetrations and fire classification, and Chapter 3 for structural, wind and seismic concerns.
Basically, Fire classification for the rooftop PV is for the system as an assembly.

The fire classification is based on the type of construction and required fire rating, and is not based on the type of roof installed. Just because someone puts a class A composition roof on a dwelling does not mean you need a class A PV system, you only need a class A PV system if the Class A is required based on the type of building or the building is located in a high fire area.
IBC section 1505.8 Building Integrated photovoltaic (BIPV) requires that where BIPV products are installed as the roof covering they shall be tested, listed and labeled for fire classification conformance with Section 1505.1 which is the for roof coverings for class A, B and C roof assemblies.
IBC Section 1505.9 requires that Rooftop mounted photovoltaic panel systems and shingles shall be tested, listed and identified with a fire classification in accordance with UL 1703. The fire classification shall comply with Table 1505.1 based on the type of construction of the building.
The dead load of rooftop PV systems, which includes the racking support systems, must be identified on the construction documents.

Both the International Building Code (chapter 16) and the International residential Code (chapter 3) require that the dead load of rooftop PV systems, which includes the racking support systems, must be identified on the construction documents. (photo source AIA Arizona)
The IBC and IRC require that the structure of roofs which support solar PV modules or panel systems must be designed to accommodate the entire load of PV modules, panels and ballast dead load, including concentrated loads from supporting structure and other applicable loads, and if applicable, snow drift loads created by the PV array.

The photo shows the difference live loads in blue and dead loads in red. The dead load will be the weight of the solar PV system and the live loads will be wind and snow.
International Building Code section 1608 requires that design snow loads shall be determined in accordance with Chapter 7 of ASCE, but the design of the roof shall not be less than that determined by section 1607 of the IBC.

Is this dead load or live load? SNOW IS A LIVE LOAD.
Determination of wind loads: The Building Code requires that wind loads on every building or structure shall be determined in accordance with Chapters 26 to 30 of ASCE 7 or provisions of the alternate all-heights method in IBC Section 1609.6

**SEAOC = Struc Eng Assc of CA. Look it up.**

Is this dead load or live load? **WIND IS A LIVE LOAD.**
The International Plumbing and International Mechanical Codes have some requirements for solar thermal systems, which includes; Solar Heating & Cooling (SHC) aka “Solar thermal”, Solar Thermal panels, Storage tanks, Heat exchangers and Roof anchors for fall protection.
The International Energy Conservation Code (IECC) is a building code created by the International Code Council in 2000. It is a model code adopted by many states and municipal governments in the United States for the establishment of minimum design and construction requirements for energy efficiency. The IECC is a model energy code, but it is written in mandatory, enforceable language, so that state and local jurisdictions can easily adopt the model as their energy code. The IECC references several ASHRAE Standards, in particular the ASHRAE 90.1 for commercial building construction, which is included as an alternative compliance path for commercial construction projects.

Section C406 of the IECC is called Additional Efficiency Package Options. It requires the inclusion of at least one item from the list of additional energy efficiency measures – one of these is on-site renewable energy. Specifically, the requirement is that the on-site renewable energy must meet one of the two following conditions:

- Provide at least 0.50 watts per square foot of conditioned floor area, OR
- Provide at least 3% of the energy used in the building for HVAC, service water heating, and lighting.

2015 IECC includes Solar Ready Appendix for Residential; 2018 IECC will also include Solar Ready Appendix for Commercial
The International Green Construction Code (IgCC) and ASHRAE Standard 189.1 provide total building sustainability guidance for designing, building, and operating high-performance green buildings (commercial only). The green codes cover areas familiar to users of LEED, such as site location, material selection and recycling, energy use, water use and commissioning.

Going forward starting with the 2018 IgCC, these documents will be merged into a single standard.
The National Electrical Code (NEC) provides the electrical code provisions which apply to solar photovoltaic electrical energy systems. This lesson will focus on the electrical code and concerns which are most likely to benefit the design professional, including; Definitions, point of connection of the PV system, main electrical service sizing, and how to approximate size of array. The primary PV specific codes are contained in article 690 and 705.

Most of the provisions in the NEC which are solar PV specific are contained in NEC articles 690 for solar Photovoltaic (PV) systems, and 705 for Interconnection of electric power production sources. Also, article 250 for grounding and bonding should be considered to facilitate PV system grounding and bonding to building steel etc.
International Fire Code (IFC)

- Fire department access
- Fire safety requirements
- Requires clear space on roof for:
  - Access paths
  - Ventilation

The International Fire Code (IFC) includes regulations governing the safeguarding of life and property from all types of fire and explosions hazards, which include and pertain to PV systems. Topics include general precautions against fire, provisions for requirements for achieving roof access, pathways and spacing of modules and equipment for fire fighter access and smoke ventilation.
The primary concern for the design professional in regards to fire fighter safety is the location of roof mounted equipment and arrays to ensure first responder safe access and egress to facilitate smoke ventilation.
For fire fighter safety the National Electrical Code requires Rapid Shutdown of PV system to be installed outside the building, typically at the electrical service or the front of the building. NEC requires signage notifying presence of solar system - location up to AHJ.
With the rapid shutdown requirement the power from the system needs to be shut off within 10 feet of the panels.

The rapid shutdown requirement is different than anti-islanding, as they serve different purposes. Rapid shutdown is a safety measure for firefighters when the building is on fire. The anti-islanding is a safety feature for utility linemen when the grid goes down.
Access and Ventilation

IFC: Access

• 6 ft. wide clear perimeter at edges of roof *
• Pathways provided in both axes

Regarding perimeter clear space, if either roof axis is less than 250 ft, clear perimeter can be reduced to 4 ft.

Pathways located in areas that can support the fire fighters; must be 4 feet clear around standpipes, ventilation hatches, roof access hatches
IFC requires provisions for smoke ventilation and gives example of solar arrays on small and large commercial buildings.
IFC 605.11.1.2.5 Requires allowance for smoke ventilation in pathways between the array sections
Prior to being put into service, to ensure a safe installation a PV system should be properly tested and commissioned. Commissioning verifies that the system has been properly installed per minimum testing procedures. Commissioning can include visual inspections, tests, user training, start up and output performance testing.

Currently, commissioning of a solar system is not required by code, but it is best practice.
Quiz & Discussion
Question 1

If the grid goes down and the sun is shining, the building will still receive energy from the PV system.

a) True
b) False
Question 1

If the grid goes down and the sun is shining, the building will still receive energy from the PV system.

a) True
b) False
Which is the best reference document for finding all code requirements for PV installations?

a) International Building Code (IBC)
b) National Electric Code (NEC)
c) International Solar Energy Provisions (ISEP)
d) International Energy Conservation Code (IECC)
Which is the best reference document for finding all code requirements for PV installations?

a) International Building Code (IBC)
b) National Electric Code (NEC)
c) International Solar Energy Provisions (ISEP)
d) International Energy Conservation Code (IECC)
The maximum size for a roof-mounted PV array is 150’ x 150’ due to:

a) Firefighter access
b) Structural loading considerations
c) Electric utility restrictions
d) Capacity of inverters
Question 3

The maximum size for a roof-mounted PV array is 150’ x 150’ due to:

a) Firefighter access
b) Structural loading considerations
c) Electric utility restrictions
d) Capacity of inverters
